Psoriasis is generally thought to be an immune-mediated inflammatory skin disease and IgE plays an important role in innate and acquired immunity. There is some evidence that IgE may take a part in the pathogenesis of psoriasis. Some studies found increased levels of serum IgE in psoriasis patients while other studies showed that the serum IgE levels in patients with psoriasis are no different to that of the normal controls [7-13]. The purpose of our study was to measure the expression of serum IgE in patients with psoriasis and normal subjects, and to analyze its association with sex, age, duration, types of psoriasis and some circulating cytokines.

Methods and Materials

Patients and controls

A case-control study was performed and all patients were from Department of Dermatology of the Second Affiliated Hospital of Xi’an Jiaotong University. Totally 98 patients with psoriasis, including 60 cases of PV, 15 cases of PE, 19 PP, 4 cases of PsA and 25 healthy controls with matched age and sex were enrolled in this study. Patients with history of atopic dermatitis, allergic diseases, parasitic diseases or systemic disease were excluded. Patients with administration of corticosteroids or immune-modulators were also excluded. The informed consent was obtained from all participants and the study was approved by the ethical committee of the Second Affiliated Hospital of Xi’an Jiaotong University.

Detection of serum IgE and cytokines

Serum levels of IgE, IL-6, IL-8 and TNF-α were measured by ELISA using commercially available kits (BD Biosciences, USA), according to the manufacturers’ instructions. The normal range for serum IgE was 0–100 IU/ml with this assay.

Statistical analysis

Statistical analysis was performed using GraphPad Prism 5.0 (La Jolla, CA, USA) and the SPSS 21.0 software (SPSS Inc, Chicago, IL). Data were expressed as mean ± SD. Student’s t-test or X²-test was used for Statistical comparisons. The Spearman’s rank test was used in correlation analyses. p < 0.05 was considered statistically significant.
Results

Serum IgE levels in psoriasis patients

The serum IgE level was elevated in 53.06% of total patients with psoriasis compared to 12% of the control group (Figure 1A). Serum IgE levels were significantly higher in psoriatic patients than those in controls ($X^2 = 13.585, P < 0.001$). Mean serum IgE concentrations was 237.01 ± 335.45 IU/ml (from 4.74 to 1490 IU/ml) in the patient group versus 46.59 ± 37.23 IU/ml (from 4.74 to 129 IU/ml) in the healthy control group. The difference was statistically significant ($P < 0.01$, Figure 1B). The Mean serum IgE concentration was 247.97 ± 328.93 IU/ml (from 6.24 to 1480 IU/ml) in male patients and 214.42 ± 352.78 IU/ml (from 4.74 to 1490 IU/ml) in female patients respectively. However, no statistical difference was found between the two groups (Figure 1C).

(B) Mean serum IgE levels in psoriasis were significantly higher than those in controls. (C) No statistical difference was observed on mean serum IgE levels from male patients compared with female patients. *$P < 0.05$, **$P < 0.01$, ***$P < 0.001$.](image)

Correlation of IgE concentration with age, duration and types of psoriasis

The disease duration of psoriatic patients in this study varied from 1 to 720 months. Patients' mean age was 40.06 ± 17.34 years. There was no correlation between age ($p > 0.05$) or disease duration ($P > 0.05$) and serum IgE level. All types of psoriasis had statistically significant elevation in the serum IgE levels compared to the controls with PE showing the highest elevation. Statistical difference of IgE concentration was also observed between PE and PV (Figure 2).

Correlation of IgE level with circulating cytokines

We observed that the serum IgE levels were positively correlated with the serum TNF-α levels in psoriasis patients (Figure 3A). However, no correlation was found between the levels of serum IgE and IL-6 (Figure 3B) or IL-8 levels (Figure 3C).

Discussion

Humoral changes that elevated serum IgA, IgG and antinuclear antibodies in psoriasis have been demonstrated within the past years [14,15]. However, studies on serum IgE’s expression in psoriasis are limited and results are paradoxical. IgE is produced by B lymphocytes and the production is regulated by T lymphocytes. IgE is generally acknowledged as a typical mediator of allergic response, which is low in healthy subjects and elevated in atopic conditions, such as eczema, rhinitis and asthma [16,17]. IgE recognizes exogenous antigens and signals through Fc receptors (FcRIs), including FcεR I and FcεR II, triggering an immunologic response. Moreover, it has been found that the levels of serum IgE significantly increase in patients with systemic lupus erythematosus, alopecia areata and other autoimmune disease [18,19].

Our data clearly demonstrated that the elevation in the serum IgE level was more frequently found in patients with psoriasis (53.06%) than in healthy controls (12%). The result is consistent with some studies

[7-11]. Yan et al demonstrated that 39% of patients with psoriasis had elevated serum IgE concentrations and they observed that lesional skin of patients with psoriasis contains more IgE+ and FceRI+ cells [20]. Chen et al reported that the serum IgE level was elevated in 46% psoriatic patients [11]. In addition, our findings were similar to a clinical study, which showed that the serum IgE concentration was increased in 42% psoriatic patients and observed that there existed no correlation between age, gender or disease duration and total serum IgE concentration [8]. Moreover, we demonstrated that all types of psoriasis had significantly increased serum IgE levels compared to the controls. In agreement with our data, a case–control study showed that the mean level of serum IgE in PE patients was much higher than that in PV patients and they suggested that a shift from Th1 to Th2 occurred in PE [10]. The IgE levels were also higher in PsA patients in our study, but the difference between PsA and PV was not statistically significant. Nevertheless, a retrospective study observed that psoriatic patients with joint symptoms had higher IgE levels and another study found completely opposite result [21,22]. Our data were also in contrast to other researches showing no increase of IgE levels in psoriasis [12,13].

Nevertheless, the mechanisms of IgE upregulation in psoriasis are still poorly understood. IgE is usually dominated by Th2 cytokines and Th2 cytokines IL-13 and IL-4 mediate class-switching towards IgE in atopic diseases [23,24]. However, IL-13 and IL-4 cannot be produced by keratinocytes and IL-13 and IL-4 were downregulated in psoriasis. There may be other mechanisms promoting the over-production of IgE in psoriasis. Psoriasis is an immune-mediated inflammatory skin disorder and there is mounting evidence that levels of TNF-α, IL-6, IL-8 and IL-17, as crucial cytokines involved in psoriasis’s pathogenesis, are elevated in psoriasis [3]. Previous studies showed that IL-8 inhibited IL-4-induced IgE production and endogenous TNF-α and IL-6 are essential for IgE production in atopic patients [25,26]. In addition, IgE promotes the autocrine production of IL-6 in human lung mast cells [27]. Recently, a study showed that IgE-secreting cells differentiation and IgE production could be directly promoted by IL-17 [28]. We wondered whether TNF-α, IL-6 or IL-8 could be, just like IL-17, involved in the regulation of IgE in psoriasis, so we measured the serum levels of TNF-α, IL-6 and IL-8 in patients with psoriasis and performed correlation analysis. Although no significant correlation was found between IL-6 or IL-8 and IgE serum levels, our study detected positive correlation between circulating TNF-α levels and IgE serum levels in psoriasis.

There exist some limitations in this study. The current study is a single center study and the sample size is relatively small, particular the sample size of PsA. We only detected the total IgE levels in patients with psoriasis, but did not measure the levels of the specific IgE levels to common allergens.

In conclusion, our data showed that serum IgE level was highly expressed in psoriasis, particularly in psoriatic erythroderma, indicating that the high serum IgE concentration may be a common feature in patients with psoriasis. The exact role that IgE plays in the pathogenesis of psoriasis should be further studied. Correlation analysis showed that serum IgE levels was positively associated with serum TNF-α. However, whether there is a causal link between TNF-α and IgE and if so, their relative roles in the causal relationship remain to be clarified.
