Abstract

In 2013, we published a review article entitled “Tumor promoters: from chemicals to inflammatory proteins”, describing that pro-inflammatory cytokines and chemokines in the cancer microenvironment induce tumor-promoting inflammation in human cancer development. We present here some significant topics based on our experiments: (i) The okadaic acid class of compounds, which are potent inhibitors of Protein Phosphatases 1 (PP1) and 2A (PP2A), showed a common mechanism of tumor promotion on mouse skin, in rat glandular stomach and in rat liver; (ii) Both 12-0-tetradecanoylphorbol-13-acetate (TPA) and okadaic acid commonly induced gene expressions of TNF-α, IL-1α and IL-1β on mouse skin, and these pro-inflammatory cytokines induced clonal growth of v-Ha-ras-transfected BALB/3T3 cells (Bhas 42), (iii) H. pylori genome contained a new TNF-α-inducing protein (Tipα) gene, and Tipα protein induced the Epithelial-Mesenchymal Transition (EMT) in human gastric cancer cells; (iv) Nucleolin on cell surface was identified as a receptor for Tipα, emphasizing gastric tumor promotion and progression of H. pylori. Finally, we discussed the broad roles of pro-inflammatory cytokines in tumor progression in relation to inflammasomes reported by other investigators.

Keywords: Cytokine; Okadaic acid; Inflammasome; Nucleolin; Tipα

Introduction

Tumor promotion was intensively studied in the 1980s, and tumor promoters were found in various organs of rodents in two-stage carcinogenesis experiments [1]. However, tumor promotion is not accepted in clinical cancer development, because tumor promotion is thought to be mechanistically different from progression. In order to close up the relationship between tumor promotion and progression, a common mechanism of tumor promoters should be generalized in various organs. Based on our evidence that okadaic acid, an inhibitor of protein phosphatases 1 (PP1) and 2A (PP2A), is a potent tumor promoter on mouse skin initiated with 7,12-dimethylbenz[a]anthracene (DMBA) as does 12-0-tetradecanoylphorbol-13-acetate (TPA), we intensively studied the mechanisms of okadaic acid in relation to TPA. The significant results of our experiments are as follows: Okadaic acid and TPA commonly induced gene expressions of TNF-α, IL-1α and IL-1β on mouse skin [2,3]; The study of tumor promotion by both okadaic acid and TPA revealed that TNF-α is an essential tumor promoter in TNF-α-deficient mouse skin initiated with DMBA [3]; Inhibitors of PP1 and PP2A induced tumor promotion on mouse skin, in rat glandular stomach and rat liver initiated with carcinogens [4]; TNF-α, IL-1α and IL-1β induced clonal growth of v-Ha-ras-transfected BALB/3T3 cells (Bhas 42) [3]; Treatment with tumor promoters commonly released TNF-α from target organs [5]. In light of our evidence showing that TNF-α, IL-1α and IL-1β act as endogenous tumor promoters and/or cancer mediators [6,7], we specifically found a TNF-α-inducing protein (Tipα) gene in H. pylori genome [8,9]. Tipα dimer bind to nucleolin on cell surface of human gastric cancer cells as a receptor [10], and are secreted in large quantities from H. pylori of gastric cancer patients [11]. The Epithelial-Mesenchymal Transition (EMT) was induced in human gastric cancer cells by Tipα [12]. The Tipα and nucleolin complex shows a strong link between tumor promotion and clinical cancer development. Since TNF-α and IL-1 are tumor-promoting cytokines, we discussed the role of inflammasome signaling for tumor promotion using apoptosis-associated speck-like protein containing a caspase recruitment domain (ASC)-KO and caspase (CASP)-1-KO mice reported by Campanelli’s group [13].

Methods

The main experimental results are cited from our publications, and the relevant literatures reviewed in this article are screened from journals and PubMed.

Results

Common mechanism of tumor promotion by inhibitors of PP1 and PP2A

Tumor promoters of the okadaic acid class, which are all potent inhibitors of PP1 and PP2A, include okadaic acid, dinophystoxin-1 (35-methylkadaic acid), calyculin A, microcystin-LR and nodularin [4]. Okadaic acid induced clonal growth of DMBA-initiated cells on CD-1 mouse skin as potently as did TPA. Okadaic acid also induced tumor promotion in male SD rat glandular stomach initiated with N-methyl-N’-nitro-N
nitrosoguanidine. Microcystin-LR and nodularin were identified as new tumor promoters in rat liver initiated with diethyl nitrosamine. All of these results showed for the first time that inhibition of PP1 and PP2A is a common mechanism of tumor promotion in various organs [4,7].

Human fibroblasts treated with both okadaic acid and TNF-α biochemically showed a similar phosphorylation pattern of over 140 proteins in two-dimensional gel electrophoresis, reported by Guy, et al. [14]. Next we found that treatment with okadaic acid, which acts as tumor promoter on mouse skin and rat glandular stomach, induced gene expressions of TNF-α, IL-1α and IL-1β on mouse skin, and released TNF-α from KATO III cells of human stomach cancer cell line [3,15]. The i.p. administration of microcystin-LR and nodularin induced TNF-α gene expression in rat liver [5], and treatments with microcystin-LR and nodularin induced TNF-α release from rat hepatocytes into the medium, while TPA did not apparently release TNF-α, nor showed tumor-promoting activity in rat liver [5]. To demonstrate the significance of TNF-α in tumor promotion, we conducted experiments with TNF-α deficient mice initiated with DMBA by topical applications of okadaic acid and TPA: Okadaic acid did not induce any tumors on skin of TNF-α−/− mice up to 19 weeks, but TNF-α+/− mice showed 100% of tumor incidence. In addition, TPA-treated TNF-α+/− mice showed 2.8 in average number of tumors, compared with 11.8 for TNF-α+/− CD-1 mice [3]. Considering the residual tumor-promoting activity in TNF-α−/− mice, we found significant expression of IL-1α and IL-1β genes as additional inflammatory cytokines for tumor promotion in TNF-α−/− mouse skin [3]. On the other hand, okadaic acid and TPA showed a similar potency of tumor promotion in IL-1−/− and IL-6−/− mice initiated with DMBA [15], suggesting that TNF-α and IL-1 are essential tumor promoters, whereas IL-6 supplements functions of other cytokines.

Carcinogenic role of TNF-α in cell transformation and tumorigenicity

Human TNF-α at a concentration of 10 ng/ml (0.6 nM) induced 1.83 average No. of foci/dish, whereas okadaic acid at a concentration of 20 ng/ml (0.02 μM) showed 1.58 and TPA at a concentration of 300 ng/ml (0.5 μM) 1.92 foci/dish in BALB/3T3 cells initiated with 3-methylcholanthrene (MCA), respectively [6]. This is important to note that human TNF-α-secreted from various cells has a more potent transforming activity than chemical tumor promoters. TNF-α also induced clonal growth in v-Ha-ras-transfected BALB/3T3 cells (Bhas 42 cells), whereas it did not induce any growth of BALB/3T3 cells without v-Ha-ras gene, indicating that TNF-α is a tumor promoter or cancer mediator in tumor development [3].

In addition, treatment of BALB/3T3 cells with human TNF-α at a concentration of 10 ng/ml (0.6 nM) significantly induced 0.33 foci/dish, even without initiation of MCA, whereas MCA at concentration of 0.1 μg/ml (0.4 μM) alone showed 0.08, and DMSO in medium was 0 [6]. Moreover, the clones from TNF-α-transformed foci of BALB/3T3 cells showed strong tumorigenicity in sites of injected mice, and also induced expression of IL-1α, IL-6, and TGF-β genes [15]. The results indicate that human TNF-α has both potent initiating and promoting activity.

TNF-α-inducing protein (Tipα) of H. pylori for gastric cancer progression

If tumor promotion can be understood as up-regulated expression of TNF-α, IL-1α and chemokine genes that are associated with activation of NF-κB, tumor promotion significantly can be closed up to the stage of progression in human cancer development. In order to prove this concept, we studied a link between TNF-α and H. pylori infection with Helicobacter pylori membrane protein 1 (HP-MP1) isolated from H. pylori strain SR 7791 [16]. HP-MP1 induced release of various inflammatory cytokines, such as TNF-α, IL-1α and IL-8, and also macrophage inflammatory protein 1α from human monocytes, although HP-MP1 is structurally unrelated to virulence factors such as cagA, vacA, and urease [16]. Next, HP-MP1 gene was transfected into v-Ha-ras-transfected BALB/3T3 cells (Bhas 42 cells, named Bhas/mpl) and v-Ha-ras-non-transformed BALB/3T3 cells (BALB/mp1), and clones of HP-MP1-transfected Bhas/mpl cells induced TNF-α gene expression more strongly that did BALB/mpl clones, and also induced cell transformation and tumors in nude mice [9].

In order to more broadly understand the function of HP-MP1 gene, we isolated HP0596 gene from H. pylori strain 26695, which was 94.5% homologous to HP-MP1 gene, and designated HP0596 protein as the TNF-α-inducing protein (Tipα) [11]. Tipα showed the same activity as did HP-MP1, and induced extensive expression of the chemokine genes, such as Ccl2, Ccl7, Cxcl1, Cxcl2, Cxcl5 and Cxcl10 in mouse gastric cancer cell line MGT-40 [17], while the inactive form of Tipα (del-Tipα) has deletion of six amino acids containing two cysteine residues) showed only marginal expression. Since Tipα is produced in various H. pylori strains, the amount of Tipα in culture broth of H. pylori was determined depending on gastric ailment. H. pylori cultured from gastric cancer patients secreted Tipα at 1.4-13.4 relative units, and those from gastritis patients secreted at 0.8-6.7 relative units [11].

Like TNF-α, IL-1β and IL-6 are critical mediators in tumorigenesis, and the stomach-specific expression of human IL-1β in transgene mice induced spontaneous gastric inflammation and cancer [18]. Since HP-MP1 (Tipα) induced release of various inflammatory cytokines, such as TNF-α and IL-1α from human monocytes [16], we conclude that pathologic elevation of a single pro-inflammatory cytokine is sufficient to induce cancer.

Nucleolin on cell surface as a receptor for Tipα

Tipα binding protein was found in cell lysates of mouse gastric cancer cell line MGT-40 using FLAG-pulldown assay and was identified as cell surface nucleolin by LC-MS analysis and flow cytometry using anti-nucleolin antibody. Nucleolin was then co-precipitated with Tipα–FLAG, but not with del-Tipα–FLAG (an inactive mutant) [10]. The direct binding of Tipα to recombinant His-tagged nucleolin fragment (284-710) was also confirmed. Pretreatment with anti-nucleolin antibody enhanced Tipα-incorporation into the cells through nucleolin internalization [10], indicating a new mechanistic insight into gastric cancer development with Tipα.

The rdel-Tipα protein is an inactive monomer, with biological activity 10-50 fold weaker than that of rTipα. The crystal structure of rdel-Tipα was determined using Multiple Isomorphous Replacements with Anomalous Scattering (MIRAS) [19], since recombinant Tipa (rTip) did not grow to the crystal. The results suggest that rTipα is secreted from H. pylori as a soluble homodimer through a secretion mechanism different from the Type IV secretion system, because neither HP-MP1 nor rTipα has a hydrophobic surface that interacts with the lipid layer of the membrane [19].

Epithelial-Mesenchymal Transition (EMT) in human gastric cancer cells by Tipα

Epithelial-Mesenchymal Transition (EMT) is theoretically understood as acquisition by epithelial cells of the phenotype of mesenchymal cells, such as fibroblasts. For example, cancer cells phenotypically are more likely to become mesenchymal cells associated with metastatic states, such as changes in cell shape and gene expression [20]. Tipα binding to surface nucleolin resulted in induction of the early metastatic states of cancer cells, such as migration, elongation and formation of filopodia associated with invasive changes in human gastric cancer cell line MKN-1, which were inhibited by the nucleolin-targeted siRNAs [12]. Tipα enhanced phosphorylation of 11 cancer-related proteins and activation of MEK-ERK signal cascade. It is of interest to note that Tipα reduced cell stiffness and increased cell motility, determined by atomic force microscopy. We think Tipα is a new inducer of EMT associated with tumor progression in human gastric carcinogenesis mediated through TNF-α [12].

Discussion

This review provided evidence that TNF-α and IL-1 are directly involved in tumor-promoting inflammation and progression. The secretion of pro-inflammatory cytokines, such as IL-1β, and IL-18 is mediated by cysteine protease caspase-1, IL-1β-converting enzyme, in activation of inflammasomes [21]. Inflammasomes are large protein complexes (>700 kDa) typically consisting of caspase-1, a Nucleotide Binding-Oligomerization Domain (Nod)-like Receptor (NLR), an adaptor protein apoptosis-associated speck-like protein containing a Caspase Activation and Recruitment Domain (CARD) domain (ASC) [22], and play divergent roles in different types of cancer reflecting the complexity of inflammation [23]. As previously reported, both IL-1α and IL-1β contribute to tumor angiogenesis and invasiveness, but the role of IL-1β is more evident in these processes [24]. In inflammatory cells, caspase-1 activation can fuel a cycle that leads to sterile inflammation and carcinogenesis, whereas in antigen-presenting cells, inflammasomes can stimulate anticancer immune responses [25].

The results of Campanelli’s group are worthwhile to note that the two-stage carcinogenesis experiments with DMBA and TPA induced the first tumor at the 5th week on caspase-1(CASP)-1 KO mice, at the 7th week on caspase-2(CASP)-2 KO mice, and at the 10th week on wild type mice, and that the levels of pro-inflammatory cytokines, such as IL-1β, IL-18 and TNFα in the tumors from CASP-1-KO and ASC-KO mice decreased when compared with wild type mice, indicating that loss of inflammasome function enhanced the process of tumor development [13]. The results indicate that inflammasomes play dual roles in the control of cancer development [13].
