Abstract
Cytokines are important for playing a major role in several inflammatory reactions resulting in development of several diseases as well as Coal Worker’s Pneumoconiosis (CWP). Coal dust exposure stimulates inflammatory response leading to enhanced cytokine release from monocytes such as TNF-alpha and IL1. These released cytokines are the key points in the pathogenesis of CWP. The present study aimed to seek the cytokine gene profiles of Turkish coal workers by genotyping and phenotyping analysis of important CWP-related proinflammatory cytokines; TNF-alpha, IL1-alpha and IL1-beta. According to the genotyping results, TNFA –238 gene polymorphism was appeared to be a risk factor in development of CWP (OR=3.79) and regarding to the phenotyping analysis, both TNF-alpha and IL1 cytokine releases from the monocytes in CWP patients were enhanced significantly compared to the healthy workers. Therewithal, LPS and coal dust stimulated TNF-alpha release were higher significantly in allele 2 carriers than allele 1 carriers in both of the groups. These data propose that coal dust-induced TNF-alpha release from monocytes may be a valuable biomarker of CWP.

Introduction
Similarly to several developing countries, coal mining is still important in Turkey contrary to the shutdown of many coal mines in developed countries. Due to the official data of the Turkey Hard Coal Enterprise, in 2015 there were 17,014 registered coal miners in whole country (Turkey Hard Coal Enterprise, 2016).

Coal worker’s pneumoconiosis (CWP) is an occupational lung disease signaled by fibrotic nodular lesions following the inhalation of coal dust. CWP is defined as the accumulation of the coal dust in lungs and the tissue’s reaction to its presence (Morgan and Seaton, 1975). Cytokines are crucial mediators of toxic and pathogenic effects seen in mineral dust exposure of humans and playing a major role in several important biological processes particularly in inflammation and immune response (Schins and Borm, 1999). TNF-alpha and IL1 cytokines are called as proinflammatory cytokines and their key roles in CWP and silicosis development are endorsed by plenty of experimental researches (Zhai et al., 1998; Corbett et al., 2002; Nadif et al., 2003; Fan et al., 2010; Lee et al., 2010; Li et al., 2011, Wang et al., 2012; Kurniwidjaja et al., 2014; Jiang PR et al., 2015). Latest studies have shown an association of TNF alpha gene polymorphisms with sensitivity to lung diseases including asthma, chronic bronchitis and fibrosing alveolitis (Huang et al., 1997; Whyte et al., 2000, Witte et al., 2002; Mukhopadhyay S et al., 2006; Yang et al., 2015; Makamure et al., 2016).

Because cytokines are key regulators of homeostatic mechanisms, possible variations in their levels or their structures may be related with the disease process (Ollier, 2004). The polymorphism commonly originates as a Single Nucleotide Polymorphism (SNP) in the network of cytokines and a vast number of SNPs have been recognized in regulatory regions of genes acting on their synthesis or degradation rates. Epidemiological researches have indicated that both pro- and anti-inflammatory cytokine SNPs are related with immune-mediated diseases (Zhai et al., 1998; Francis et al., 1999; Franceschi et al., 2001; Yucsesoy et al., 2002; Kim et al., 2003; Fan et al., 2001; Kim et al., 2002; Okuma et al., 2002; Yucsesoy et al., 2005; Jonth et al., 2007; Fan et al., 2010; Li et al., 2011, Wang et al., 2012, Makamure et al., 2016).

Subsequent to coal dust exposure, lung tissue responds by starting three types of phenomena: an accumulation and activation of inflammatory cells in lower respiratory tract, fibroblast proliferation and an increased synthesis of extracellular matrix components (Vanhee et al., 1995). Macrophage-derived cytokines are the key points in coal dust inflammation. Presence of persistent stimulus and chronic release of cytokines may conclude in autoimmune and inflammatory diseases as well as CWP or silicosis. Recent records have displayed that following the coal dust exposure of alveolar macrophages, a significant release of TNF-alpha and IL1 from blood monocytes occurs (Lasalle et al., 1990; Jorna et al., 1994; Zhai et al., 1998; Kim et al., 1999; Borm et al., 2005; Jonth et al., 2007; Fan et al., 2010; Li et al., 2011, Wang et al., 2012, Makamure et al., 2016).
and Schins, 2001; Wang et al., 2005; Zhang et al., 2015).

Several researches have pointed out that TNF-alpha release from blood monocytes differentiates coal workers with respiratory and pulmonary effects of coal dust (Jorna et al., 1994; Zhai et al., 1998). According to the data of these studies, release of monocytes TNF-alpha is a valid means to CWP prognosis beneath history and X-rays when carefully applied. Comprehension of the underlying mechanisms of the CWP aetiology was fundamental in offering numerous biomarkers evaluated to appraise the effects following exposure to coal dust. Human studies exhibited some of these offered biomarkers for CWP including TNF-alpha released from monocytes and TNF-alpha polymorphism (blood cellular DNA) and also they were defined as biomarkers of sensitivity (Gulumian et al., 2006).

In this study, we aimed to follow two assumptions: First, CWP-associated pro-inflammatory cytokines (TNF-alpha, IL1-alpha and IL1-beta) gene polymorphisms related with CWP in a group of Turkish coal workers. Second, these gene polymorphisms have an important role on the release of these cytokines from blood monocytes due to the coal dust exposure in homozygous and minor variant allele carriers. To check over these assumptions, we gathered coal workers having a heavy dust exposure background and searched the stated cytokines releases from blood monocytes by genotyping and phenotyping analyses.

Materials and Methods

All the individuals were gathered from Kozlu/Zonguldak region of Turkey where coal is densely mined. For genotyping analyses, subjects were categorized into two groups: 67 retired coal worker with CWP as patients and 92 workers without any CWP evidence as controls. All active coal workers were chosen from the mining part of the mine (except the coal face or stope) having a mean coal dust exposure (0.07-1.25 mg/m³ respirable coal dust fraction). Mean coal chemical properties of Kozlu mines were as follows: 55% carbon, 28% volatile substances, 10% ash, 7% moisture and also about 47% of the ash came out of crystalline silica. After defining the genotype profiles of the all individuals, their profiles were inspected cautiously for studied cytokine gene polymorphisms. Patients frequently (at least 3 of the 5) bearing homozygous 1/1 allele and genotype frequencies between controls and cases. No interactions were obtained between allele and genotype frequencies between controls and cases. No interactions were obtained between allele and genotype frequencies between controls and cases.

DNA preparation and genotyping

10 ml whole bloods of all studied individuals were collected by venipuncture in tubes containing heparin. Afterwards, DNA isolation were performed by Promega Wizard Genomic DNA Purification kit due to the manufacturer’s instructions and all the DNA samples were stored at -20°C till analyses. Genotyping of TNF-alpha -308G/A, TNF-alpha -238G/A, IL1-alpha +4845C/T and IL1-beta +3953C/T gene polymorphisms were carried out using a Polymerase Chain Reaction-Restriction Fragment Length Polymorphism (PCR-RFLP) method due to the formerly mentioned protocols with minor modifications from Ates et al., (2008). PCR reaction products were departed by gel electrophoresis on a 10% polyacrilamide-TBE gel at 200 V for 40 min and then viewed via an UV illumination following staining with ethidium bromide solution.

Monocyte isolation and measurement of cytokine release

The isolation of monocytes from the peripheral blood was performed due to the technique of Strobner (1994). The cytokine release levels from adherent monocytes supernatants (5 x 10⁴) were calculated by Enzyme-linked Immunosorbtent Assay (ELISA) without a stimulant (spontaneous) or afterwards 18 h of incubation with coal dust (5 mg/ml) and LPS (1000 ng/ml) at 37°C and 5% CO₂.

Statistical analysis

For whole of the statistical analyses, we exerted the version no 15 of the SPSS programme (SPSS Inc., Chicago, IL, USA). Possible significant associations between polymorphic variants and disease situation were commentated by χ² test and Fischer exact test where suitable. The χ² test was performed to check against allele and genotype frequencies between controls and cases. Odds ratios (OR) and incorporated 95% Confidence Intervals (CI) were evaluated by logistic regression. A p-value <0.05 was regarded as significant.

Results

(Table 1) demonstrates the demographic output of all the studied individuals. No interactions were obtained between the CWP and the parameters of age and smoking following the multiple linear regression method. On the other hand, work period was found to be associated with the development of the disease.

(Table 2) indicates the distribution of TNF-alpha and IL1 genotypes. Whole SNPs in both controls and cases were in the Hardy-Weinberg equilibrium. Entire risk of disease was significantly higher only with TNF-alpha (-238) variant (OR=3.79, 95% CI: 1.37-10.46). In regards of TNF-alpha (-308) variant, an enhancement risk for CWP was observed however it was not significant (OR=1.37; 95% CI, 0.73-2.58). No significant relationship was seen between neither the IL1-alpha nor IL1-beta variants with CWP.

(Table 3) represents the allelic distribution of the group of CWP patients matched with controls. The development of the disease was ascended in allele 2 carriers than the ones hauling allele 1. The basal, the LPS and the coal dust-caused cytokine release were seized up for appraising the in vitro cytokine release
from the blood lymphocytes. As obviously seen from the data given in Table 4, there was a significant association between the patients hauling allele 2 compared to those of controls (p < 0.05).

In (Table 4), TNF-alpha and IL1 cytokine releases from blood monocytes of controls and CWP patients were demonstrated. The release order of studied cytokines was as spontaneous → coal dust-induced → LPS-induced. The release of these cytokines in CWP patients were significantly enhanced in contrast to the controls. Conversely, the coal dust-induced release of TNF-alpha in allele

In this research, we gathered a group of coal workers with CWP who had a common history to heavy dust exposure. According to the data, we sighted significantly higher allele 2 in both study groups. In despite of an increase of the IL1 cytokines release in allele 2 carriers in all subjects, no significant distinction was observed. Smoking was also considered as a confounding factor but no relationship was found of the possible effects of smoking on the release of cytokines.

**Discussion**

In this research, we gathered a group of coal workers with CWP who had a common history to heavy dust exposure. According to the data, we sighted significantly higher allele frequencies of -238A in patients contrast to controls. Moreover, it seems that TNF-alpha is an important parameter in development of CWP more than IL1. TNF-alpha -238A variant should be kept in
A Genotyping and Phenotyping Study Concerning the Possible Effects of Some Inflammatory Cytokine Gene Polymorphisms on the Development of Coal Workers' Pneumoconiosis

mind as a risk parameter in development of the disease and there is an enhancing effect of TNF-alpha cytokine gene polymorphism on release of it from the blood monocytes.

Even though its pathophysiological mechanisms have not been fully identified, coal dust has been known as the most important factor for the development of CWP. Chronic diseases induced by inflammation including CWP are multi-factorial ones directly affected by both genetic and environmental parameters. Polymorphisms such as genetic factors can switch the size or severity of the disease. In regards to this, SNPs are important affecting the amount of inflammatory cytokines which have been related with too many different chronic inflammatory and autoimmune diseases (Zhai et al., 1998; Franceschi et al., 2001; Yucesoy et al., 2001; Ates et al., 2008; Wang et al., 2012; Yang et al., 2015; Makamure et al., 2016).

TNF-alpha is a major cytokine relative to CWP’s inflammatory and fibrotic processes (Schins and Borm, 1999). Variations at -238 and -308 have been suggested to be responsible for the modification of TNF-alpha production (Fan et al., 2010). A relationship between -308 variant and CWP in Europeans (Zhai et al., 1998), in South Africans (Corbett et al., 2002), in Japan (Wang et al., 2005) and in Chinese (Fan et al., 2010) has been observed. In these researches, the possible effect of TNF-alpha -238 variant was also studied and due do the data, only Corbett et al., (2002) and Ates et al., (2008) have obtained distinct relationship between this variant with the development of CWP. In respect to our research, according to the genotyping data, we found -238 variant to be a powerful risk factor for CWP. On the contrary, we observed an enhancement risk factor for -308 variant in patients compared to controls but it was not significant.

IL-1 is one of the most studied proinflammatory cytokines as similar as TNF-alpha. There are many researches related with the possible effects of IL1 gene polymorphisms on several pulmonary and autoimmune diseases except CWP. In our study, we did not observe any significant relationship with IL1-alpha variants and the development of CWP. For each polymorphism, the odds ratio of disease and associated 95% confidence intervals for individuals carrying alleles 2 were reported for the CWP patients, using logistic regression models with adjustment for age, years of exposure and smoking.

Latest in vitro release researches have indicated that pro-inflammatory cytokine levels of TNF-alpha and IL1 were triggered in CWP (Schins and Borm, 1995; Zhai et al., 1998; Kim et al., 1999). According to our data, we found an enhanced release of TNF-alpha from blood monocytes after coal dust and LPS stimulation in contrast to spontaneous release in both controls and patients. The level of released TNF-alpha was significantly increased in allele 2 carriers than allele 1 hauliers. These results are alike to the data of Zhai and co-workers (1998) and Kim and co-workers (2002). On the other hand, even though there was a triggering effect in the release of IL1-alpha and IL1-beta, no significant differences were found between both allele 1 and 2 hauliers. It was obviously observed that in patients, the levels of cytokine release from monocytes were about 3-4 fold higher than controls. These findings indicate an association between coal dust exposure and cytokine releases in the development of CWP.

In this study, smoking did not point out any significant contribution to the development of CWP.

Due to the limited sample size of the studied groups, we need to comment these findings cautiously as precursors. Further researches performed with sufficient “n” number are needed to verify these results.

In conclusion, due to our genotyping findings, TNFA –238 gene polymorphism was appeared to be a risk factor in development of CWP (OR=3.79) and regarding to the phenotyping analysis, both TNF-alpha and IL1 cytokine releases from the monocytes in CWP patients were enhanced significantly compared to the healthy workers. Therewithal, LPS and coal dust stimulated TNF-alpha release were higher significantly in allele 2 carriers than allele 1 carriers in both of the groups. These data propose that coal dust-induced TNF-alpha release from monocytes may be a valuable biomarker of CWP. Further intended comprehensive researches with a vast number of individuals should be performed to illuminate the underlying mechanisms and possible effects of these cytokine gene polymorphisms.
