Abstract

Purpose: To determine the epidemiological, clinical and therapeutic aspects of post-traumatic lesions of the posterior segment.

Patients and methods: A retrospective study was conducted during the period from 1 January 2011 to 31 December 2013. We identified the records of patients with post-traumatic lesions (non-surgical) of the posterior segment.

Results: Injuries accounted for 7.05% of consultations including 9.3% interesting the posterior segment. The mean age was 23.14 years. The age group of 16-45 years was the most affected with 56.14% of cases.

The sex ratio was 6.13. More than 25% of patients had consulted more than a year after the trauma. The decrease in visual acuity was the most frequent reason for consultation with 96.49% of cases. Circumstances of trauma were dominated by brawls. Metal objects and stone jets were the most common causal agents. Closed globe injuries represented 44 cases (77.19%). In these cases the lesions of the posterior segment were dominated by retinal detachment (36.37%) followed by fibrous vitreous organizations (29.55%). In open globe injuries, the lesions of the posterior segment were dominated by retinal detachment (61.54%), followed by vitreous hemorrhage (30.77%). We noted as complications and sequelae two cases of endophthalmitis, 13 adhesions iridocristalliniennes and 2 cases of ocular physis. Ten patients (17.54%) were hospitalized. Nineteen patients had medical and surgical treatment. Among them, eight patients had ocular suture, and nine patients, cataract surgery. Two patients had a vitrectomy, and one patient had a scleral buckling. The final visual acuity could be assessed only in 24 cases (42.10%). It was superior or equal to 5/10th in one case (4.2%), and less than 1/10th in 23 cases (95.8%).

Conclusion: Post-traumatic lesions of the posterior segment are varied and can cause significant anatomical and functional impact. Their care remains difficult. Increased awareness of the population would reduce the incidence and improve the coverage.

Keywords: Post-traumatic lesions; Posterior segment

Introduction

Eye injuries are a major public health problem. For one of their sometimes serious complications, but also by their care remains difficult despite advances in surgery.

The retrospective study conducted at the Hospital Aristide Le Dantec was to determine the epidemiological, clinical and therapeutic post-traumatic lesions of the posterior segment of the globe.

Patients and Methods

During the period from 1 January 2011 to 31 December 2013, we identified the records of patients with post-traumatic lesions (non-surgical) of the posterior segment.

On the following data sheet investigations were identified, marital status, consultation deadline, histories, clinical signs, results of Ultrasonography of the posterior segment, the received treatment and post-treatment changes.

Results

Frequency

During the study period, injuries accounted for 7.05% of consultations including 9.3% interesting the posterior segment.

Demographic data

The mean age was 23.14 years with extremes of 4 and 75 years. The subjects from 0 to 15 years old represented 20 cases, including 16 male (80% of cases). The age group of 16-45 years was the most affected with 32 cases (56.14% of cases).

The sex ratio was 6.13. The distribution of patients according to age group and gender is presented in (Table 1).

Table 1: Distribution according to the sex and the age bracket.

Clinical data

Histories

Three patients (5.26% of the cases) reported histories or a particular field, two cases of phacoexérèse, and a case of glaucoma.

Consultation deadline

It ranged between 1 and 12 years.

More than 25% of patients had consulted more than a year after the trauma. The various consultation deadlines are reported in (Figure 1).

The reasons for consultation

The decrease in visual acuity was the most frequent reason for consultation with 55 cases (96.49% of cases). It was associated with redness and pain in 37 cases (64.91% of cases).

Other reasons for consultation in order of frequency, watery eyes (19.3%) photophobia (17.54%), and bleeding (5.26%).

Circumstances of trauma

These circumstances were identified in 49 patients (5.46% of cases). They were dominated by brawls in men. Domestic accidents were the first circumstance of occurrence in women, while playful accidents were the first circumstance in children. Different circumstances are shown in (Figure 2).

Nature of the traumatic object

The causal agent was not specified in almost 18% of cases. In other cases, metal objects and stone jets were the most common causal agents. The various traumatic agents are summarized in (Figure 3).

Laterality

The disease was unilateral in 100% of cases. The right eye was achieved in 30 cases (52.63% of cases).

The initial visual acuity

Visual Acuity (VA) was not specified in 5 cases. For others, it was less than 1/10th in 48 patients (92.3% of cases), it was between 1/10th and 5/10th in 2 patients (3.85% of cases) and greater than 5/10th in 2 patients (3.85% of cases).

Type of trauma

Closed globe injuries represented 44 cases (77.19%). In these cases it was noted besides the lesions of the posterior segment, an adnexal reached in 40 cases (90.9%) and the anterior segment in 35 cases (79.55%). The lesions of the posterior segment were dominated by retinal detachment (36.37%) followed by fibrous vitreous organizations (29.55%).

Open globe injuries regrouped ten penetrating wounds, two intraocular foreign bodies and rupture of the globe. Adnexal and anterior segment injuries were reported in 100% of cases. The lesions of the posterior segment were dominated by retinal detachment (61.54%), followed by vitreous hemorrhage (30.77%). The various lesions of the posterior segment are reported in (Table 2).

Complications and sequelae

We noted two cases of endophthalmitis, 13 adhesions iridocrystalliniennes and 2 cases of ocular phtyse.

Therapeutic

Treatment

Ten patients (17.54%) were hospitalized. Forty-nine patients had medical treatment. Nineteen patients had medical
and surgical treatment. Among them, eight patients had ocular suture, and nine patients, cataract surgery. Two patients had a vitrectomy, and one patient had a scleral buckling.

**Post treatment visual acuity**

The final visual acuity could be assessed only in 24 cases (42.10%). It was superior or equal to 5/10th in one case (4.2%), and less than 1/10th in 23 cases (95.8%).

**Discussion**

**Frequency**

The frequency of injuries was 7.05%, which approximates to Oyoua results in Côte d’Ivoire [1] which reported a rate of 7.7%. Kante [2] found a rate was much lower (1.22%). The lesions of the posterior segment represented 9.3% of all injuries. Our figures are higher than those described in the literature [3, 4].

**Demographic data**

Male dominance was marked with a sex ratio of 6.13. This dominance was even more pronounced for the group of 0-15 years with 80% of male patients. Other series found this male dominance [5, 6, 7]. This could be explained by the fact that men were more often involved in traumatic to risk activities.

The mean age was 23.14 years. Khalki [5] reported a mean age of 24.36 years, while Seck [8] found a higher age 34.6 years. The most affected age group was that of 16-45 years, which approximates the results of Kaya [9] which noted a peak between 16 and 35 years. The age group of 0-15 years accounted for 35.99% of the cases in our series, which joins other data sets [5, 8].

**Clinical data**

**Consultation deadline**

Only 8.77% of patients had consulted in 6h after injury. Lam [6] found a rate close to 10%. About 20% of our patients had consulted before the 24th hour. This figure remains lower compared to other African series [6, 10] which reported a rate above 50%. Patients who had consulted more than a year after the trauma accounted for over 25% of cases, and 24 patients (42.1% of cases) had retinal detachment. Trigui [11] noted that the retinal detachment occurred in over 50% of cases, a year after the trauma. Verin [12] reported that in developing countries, the consultation deadline for ocular trauma was often delayed due to the ignorance of populations to their severity and the necessity of an urgent coverage.

**Circumstances of occurrence**

Brawls were the first circumstance of occurrence the traumas of the posterior segment. They also occupied the first place in other series [5, 11]. Playful accidents were the second circumstance all ages but figured first in children. Which joined other data [6, 13], which recorded the playful accidents were the main circumstances of trauma in children. Domestic accidents were the third circumstance as well as for Lam [6]. In other series they represented the first one [14] or the second circumstance [5]. Public road accidents were placed fourth. They represented the first circumstance for Tchabi in Benin [15], while for others [5, 6], they were only the fifth occasion. Workplace accidents were the fifth occasion with a frequency of 15%. They ranked fourth but with a lower frequency for Lam [6] and Khalki [5]. Ngondi [16] reported that the worker is not sufficiently accountable for the risks of accidents. He noted the importance of preventive eye exams and development of business advocacy strategies.

Stone jets and metal objects were the main traumatic agents with a rate close to 16%. Metal objects were the first one cause almost 20% of cases for Gbe [7]. Khalki [5] found the stone jets as first one cause with a rate close to 19%. Lam [6] found the punches as the first one cause with a frequency of 16%, which is almost double our results, where punches occupied only the fourth rank.

Thus the nature of the traumatic agents and frequency vary depending on the environment and socio-cultural habits.

**Laterality**

The disease was unilateral in 100% of cases, joining Gaboune results [17]. Other series [6, 8] reported bilateral involvement, but with a lesser frequency.

**Type of trauma**

Closed globe injuries accounted for over 75% of our series, joining the other data [6, 18] who reported that predominance. The retinal detachment was the most common injury with 24 cases (42.1% of cases), joining Frau [19] who found a rate of 43%. This rate remains very variable depending on the series [5, 20]. In the open globe injury, retinal detachment were found in 8 cases (47.06% of cases), joining the Rouberol data [21].

The vitreous hemorrhage was found in 15 cases (26.32% of cases), which joined the Aberkane data [20].

An optical atrophy was found at 3 patients (5.26%) who were victims of violent trauma (brawl, fall). Levin [22] reported that the violent trauma at the young men was the most common cause of traumatic optical neuropathy.

---

In 3 cases (5.26%) we found a retinal edema. Frau [19] noted a rate near twice higher.

Two patients had macular hole (3.51%). These data joining those of Aaberg [23]. We objectified 2 posterior vitreous detachments (3.51%). This rate was significantly lower than the Savi data [18], who reported rates of at least 5 times higher.

Choroidal rupture was found in 1 case (1.75%). These data are significantly lower than those of Khalki [5].

**Therapeutic**

Forty-nine patients had medical treatment. Nineteen patients had medical and surgical treatment. Among them, eight patients had ocular suture, and nine patients, cataract surgery. Two patients with vitreous organization had a vitrectomy, and a patient with retinal detachment had scleral buckling.

Both patients presenting a macular hole had no surgical treatment. One of them had consulted less than a month after the injury, the monitoring was recommended owed made by the possibility of spontaneous closure [24]. For the other patient, the deadline consultation exceeding one year. This seniority was a factor of bad prognosis poor prognosis, with a surgical success rate lower than 50% [25].

The post treatment visual acuity could be assessed in 24 patients (42.10%). It was less than 1/10th in almost 96% of cases. This figure is very high compared to the data of the literature [5, 6, 11] where the rate does not exceed 60%. Our results can be explained by the already weak pre therapeutic visual acuity with over 90% of patients with lower acuity at 1/10th. Another explanation is that the lesions of the posterior segment were worse prognosis as confirmed by Kuhn [14]. But also bias the study related to incomplete records with a final visual acuity evaluated in less than 50% of patients.

**Conclusion**

Post-traumatic lesions of the posterior segment are varied and can cause significant anatomical and functional impact. Increased awareness of the population would reduce the incidence and improve the coverage.
