Abstract

Background: Central nervous system injury associated with perinatal asphyxia is called as Hypoxic Ischemic Encephalopathy (HIE). HIE is the most important neurological problem occurring in the perinatal period.

Objective: To evaluate newborns with birth asphyxia based on APGAR scores and to correlate it with development of clinical HIE.

Method: A prospective clinical study of 50 asphyxiated newborns. The assessment of birth asphyxia was performed using 1 minute APGAR score<5 and/or 5 minutes APGAR score<7. The neurological assessment of these 50 asphyxiated newborns was done using Sarnath and Sarnath Staging of HIE. The correlation between birth asphyxia and HIE was assessed.

Results: HIE occurred in 21/50 (42%) asphyxiated newborns. According to HIE staging, HIE-I cases were 5 (23.81%), HIE-II were 7 (33.33%) and HIE-III were 9 (42.86%). Death occurred in 7 (33.33%) cases of HIE. There was no statistical significant correlation between HIE with gender, weight for gestation, maternal factors and foetal factors. However significant correlation between HIE-II with gestation (p<.05) and HIE-III with NVD and LSCS (p<.05) was noted. There was also significant correlation between Apgar score at 1 minute with HIE-III (p<.05) and Apgar score at 5 minutes with HIE-II (p<.02) and HIE-III (p<.05).

Conclusion: Most newborns with birth asphyxia did not develop HIE. But those who did develop had severe HIE-II. There was significant correlation between severity of birth asphyxia and development of severe form of HIE. As the 1 minute and 5 minutes Apgar score decreased the severity of HIE increased.

Introduction

Perinatal asphyxia refers to a condition during the first and second stage of labour in which impaired gas exchange leads to foetal hypoxemia, hypercarbia and metabolic acidosis [1, 2]. Perinatal asphyxia is a major factor contributing to perinatal and neonatal mortality [3]. Cerebral palsy is the most important long term outcome of birth asphyxia and may be accompanied with mental retardation, seizure disorder or other neurological and sensory (visual or auditory) disabilities [4]. It is the fifth largest cause of under-5 deaths (8.5%) after pneumonia, diarrhoea, neonatal infections and complications of preterm birth [3]. In 1952, Dr. Virginia Apgar devised a scoring system that was a rapid method of assessing the clinical status of the newborn infant at 1st minute of age [5]. It was designed to be a guide to the need for resuscitation of newborns and developed as an objective tool that measured five signs of physiologic adaptation. This scoring system quickly gained near universal acceptance. The Apgar score can somewhat predict mortality, however, it is not a tool to be used alone in determining neurologic outcomes of infants who survive [6].

Most of the births in developing countries occur at home usually attended by untrained birth attendants. Failure to initiate and sustain breathing immediately after delivery has been associated with severe foetal hypoxia or ischemia which can manifest in newborn as encephalopathy and may result in neonatal death or permanent motor and mental disability [3]. This injury has been termed as Hypoxic Ischemic Encephalopathy (HIE). The foetus who experiences a significant hypoxia episode is at risk of developing HIE or other end organ damage and its sequelae [7]. HIE is of concern in an asphyxiated neonate because it can lead to serious long term neuromotor sequelae among survivors [7]. The HIE score based on modified Sarnath scoring system is a clinical tool comprising of a set of clinical signs associated with CNS dysfunction and is used to assess status of a child following birth asphyxia [8]. Several new technologies like CT, MRI have become available to determine cerebral damage during perinatal period and predict long term neurological outcome. These modalities are however not readily available in many neonatal units in developing countries like India and hence the centres heavily rely on clinical assessment and scoring systems to predict HIE or neurological injury [9]. The present study tries to note the frequency of HIE in asphyxiated newborns based on the current neurological scoring system and tries to evaluate the prediction of degree of neurological injury based on severity of asphyxia sustained.

Material and Methods

The prospective clinical study was carried out in neonatal unit of Maharishi Markandeshwar Institute of Medical Sciences.
A Study on Incidence of Clinical Hypoxic Ischemic Encephalopathy Injury in Newborns with Perinatal Asphyxia

Inclusion criteria

- All neonates with birth asphyxia born in Labour Unit of our hospital.
- Exclusion criteria:
- Outborns
- Inborn neonates with congenital malformations, infections, chromosomal abnormalities, inborn errors of metabolism, dysmorphic syndromes and still born.

Birth asphyxia was defined using Apgar score at 1 minute <5 and/or Apgar Score at 5 minutes <7. Complete obstetric history was obtained and examination of the babies was performed after delivery. The neonatal clinical course was followed up prospectively and data was recorded on pre-designed proforma. Informed written parental consent was obtained for all infants before entry in the study, which was approved by the ethical committee.

Detailed neurological examination of asphyxiated newborns was performed after 24 hours of birth until discharge or death. The stage of encephalopathy was assessed according to Sarnath and Sarnath Clinical staging of HIE. Depending on the neurobehavioral signs neonates were divided in 3 stages I, II and III (Mild, moderate and severe). Further, the relationship between birth asphyxia and HIE was also studied in all included newborns.

Statistical Analysis

Appropriate data entry and statistical analysis were performed on Microsoft excel and SPSS software. Data was summarized using descriptive statistics. Categorical variables are presented as number and percentage. Chi-square test was used to compare the association among two or more categorical variables. All statistical tests were two-tailed and alpha level of significance was set less than 5%. A p value of <0.05 was taken as statistically significant.

Results

Demographic and Clinical profile

Among 50 newborns 30 (60%) were males and 20 (40%) were females and 31 (62%) were term and 19 (38%) were preterm as per gestational age. As per weight for gestation, 42 (84%) were appropriate for gestational age (AGA) and 8 (16%) were small for gestational age (SGA). The various maternal, perinatal and foetal factors associated with asphyxia in newborns are highlighted in figure 1. 32/50 (64%) were born by normal vaginal delivery (NVD) without instrumentation, 7 (14%) with instrumentation and 11 (22%) by lower segment caesarean section (LSCS). As per Sarnath and Sarnath clinical scoring for neurobehavioral signs and symptoms, 21 (42%) had evidence of HIE. Upon grading, severe HIE (HIE-III) was most common, seen in 9/21 (42.86%) cases table 1. Among 21 cases of HIE, death occurred in 7 (33.33%) cases, 12 (57.15%) were alive till last follow up and 2 (9.52%) cases left against medical advice (LAMA).

Correlation between HIE and APGAR score

Tables 2 and 3 highlight correlation of HIE with APGAR scores at 1 and 5 minute respectively. There was a statistically significant correlation between HIE-III with APGAR at 1 minute (p=0.05) noted as all 4 cases with an APGAR of 0-2 had severe HIE (HIE-III) as compared to none with a score of 5 and only 23.8% with a score of 3-5. There was also a statistically significant correlation noted between HIE-II (p=0.05) and HIE-III (p=0.01) with APGAR score at 5 minutes table 3.

Discussion

This study was conducted to note the frequency of HIE in asphyxiated newborns based on the current neurological scoring system and to correlate the development of hypoxic ischemic encephalopathy in asphyxiated newborns various fetal, perinatal and maternal variables. Fifty asphyxiated newborns were studied, all of them fulfilling the inclusion criteria. Out of these asphyxiated newborns born in our hospital, males were 30 (60%) and females were 20 (40%) and as per gestation, 31 (62%) were term and 19 (38%) preterm. Dalal A et al [9] in their study had 168 (52.5%) males and 152 (47.5%) females and 87% were term neonates and 13% preterm neonates. In a similar study by Dag et al [10] 20 (55%) were males and 16 (44%) were females and 32 (88.8%) were term newborns and 4 (11.11%) preterm newborns. In present study preterm newborns could be low due to less of preterm deliveries nowadays because of better antenatal care and visits and assessment. According to weight for gestation, AGA were 42(84%) and 8 (16%) SGA in our study. This may be due to better antenatal care and follow up. 52.8% AGA

Inference:
1. HIE stage II is significantly correlated with APGAR at 5 minute with p<0.05 tested with Pearson Correlation Test.
2. HIE stage III is significantly associated with APGAR at 5 minute with p<0.01 tested with Chi Square Test and p<0.01 tested with Pearson Correlation Test.

Correlation between HIE and APGAR score at 5 minutes.

- APGAR score at 5 minutes predicts the better outcome than 1 minute score. 10 minutes score should also be assessed to predict the better neurodevelopment outcome and to assess whether additional resuscitative efforts are required if APGAR score is 0 at 10 minutes.
- HIE scoring system should be used to assess outcome of asphyxiated newborns as sophisticated or expensive equipment is not required. But other parameters to assess HIE should also be considered if required and also according to availability.
